

ABSTRACT OF THE DISCLOSURE

A multi-compartmented propel container is provided for a viscous product, such as gels, creams, etc. that maintain separate certain components of the product during storage and allows combination of the components just prior to use. The container includes multiple compartments and a turning mechanism that propels the components of the product simultaneously from the separate compartments into a dispensing outlet where the components come together in admixture and are then ready for application by a user. The turning mechanism also can be structured to allow for repel of the product components, if desired.
